## Rangeland health reference sheet

Interpreting Indicators of Rangeland Health is a qualitative assessment protocol used to determine ecosystem condition based on benchmark characteristics described in the Reference Sheet. A suite of 17 (or more) indicators are typically considered in an assessment. The ecological site(s) representative of an assessment location must be known prior to applying the protocol and must be verified based on soils and climate. Current plant community cannot be used to identify the ecological site.

Composition (Indicators 10 and 12) based on	Annual Production

## **Indicators**

- 1. **Number and extent of rills:** Slopes on this site are typically less than 10%, but may range as high as 55%. Rills should not occur in the Taller Bunchgrass State on slopes less than 15%. As slope increases so will the number and length of rills. Rills on steep slopes (>35%) should be <5 feet long.
- 2. **Presence of water flow patterns:** Water flow patterns are generally not evident in the reference state especially on slopes <4%. Following occasional (5 30 % probability), heavy thunderstorms and winter thaw events, short, sinuous, discontinuous flow patterns may be

10.	Effect of community phase composition (relative proportion of different functional groups) and spatial distribution on infiltration and runoff: The reference plant community (1.1) is dominated by rough fescue which will maximize infiltration and minimize runoff throughout the site. With the increase of Idaho fescue in Plant community (1.2) infiltration may slightly decrease and runoff may slightly increase but overall this plant community will have only minor affects on infiltration and runoff.
11.	Presence and thickness of compaction layer (usually none; describe soil profile features which may be mistaken for compaction on this site): A compaction layer would not be expected on this ecological site.
12.	Functional/Structural Groups (list in order of descending dominance by above-ground annual-production or live foliar cover using symbols: >>, >, = to indicate much greater than, greater than, and equal to):
	Dominant: Plant community 1.1 - Taller cool season bunchgrasses (Idaho fescue) >> mid-stature cool season bunchgrasses (Idaho fescue) > cool season rhizomatous grasses (western wheatgrass), shortgrasses (prairie junegrass) and grasslikes (sedges) = perennial forbs > shrubs. Plant community 1.2 – Rough fescue and Idaho fescue share dominance – the other functional/structural groups will remain the same in descending order.
	Sub-dominant:
	Other:
	Additional:
13.	Amount of plant mortality and decadence (include which functional groups are expected to show mortality or decadence): Plant mortality for all functional groups will be low, but there will be some natural mortality of functional groups over time. Prolonged droughts and/or excessive rest may show increases in mortality and decadence for all plant

surface horizon is 4 to 8 inches thick.

groups.

14.	Average percent litter cover (%) and depth (in): Note: the majority of the litter in the plant community in the Taller Bunchgrass State will be non-persistent.
15.	Expected annual annual-production (this is TOTAL above-ground annual-production, not just forage annual-production): 1100 #/acre – 1700 #/acre for the reference community (1.1) with a RV of 1350 #/acre.  Production varies based on effective precipitation and natural variability of soil properties for this ecological site.
16.	Potential invasive (including noxious) species (native and non-native). List species which BOTH characterize degraded states and have the potential to become a dominant or co-dominant species on the ecological site if their future establishment and growth is not actively controlled by management interventions. Species that become dominant for only one to several years (e.g., short-term response to drought or wildfire) are not invasive plants. Note that unlike other indicators, we are describing what is NOT expected in the reference state for the ecological site: Cheatgrass, knapweed spp., leafy spurge, sulphur cinquefoil, dalmatian toadflax, houndstongue, whitetop, Canada thistle, Japanese brome, broom snakeweed, fringed sagewort, salsify and dandelion.
17.	Perennial plant reproductive capability: All native plants are capable of reproducing sexually and/or vegetatively.
